PLANE SHOCK INITIATION OF DETONATION: COMPUTER SIMULATION  
OF A GAS-GUN EXPERIMENT

by

Wildon Fickett and Jack D. Jacobson

ABSTRACT

A numerical calculation of the early stages of plane-shock initiation in the high explosive PETN using very simple constitutive relations qualitatively reproduces the experimental results. The calculated results should be a useful guide to the planning and interpretation of experiments, and may be used to quantitatively assess the methods of analysis which deduce other variables from the experimental pressure-gauge records.

I. INTRODUCTION

Shock initiation of condensed explosives is commonly studied by taking pressure histories from quartz and Manganin gauges. Other variables may then in principle be determined by analysis of the gauge records, under some reasonable assumptions concerning neglect of transport properties.

In thinking about such an experiment it is useful to have a calculation which at least qualitatively reproduces it so that one can have some idea of what is going on "behind the scenes". The calculation can also serve as a quantitative test case for the method of analysis to be used on the experimental data.

Our calculation supplements the experimental work of Wackerle and Johnson on PETN.<sup>1</sup> With simple constitutive relations we are able to qualitatively reproduce the early motion. These would probably do less well if the calculation were extended to cover the entire process--that is, through the final transition to high-order detonation, although the calculated distance of run to high-order detonation is about right.

II. CONSTITUTIVE RELATIONS

The constitutive relations consist of two parts: an equation of state for the reactant-product mixture and a reaction rate. A sufficiently general representation for our purpose is

$$p = p(\rho, e, \lambda)$$

$$d\lambda/dt = r(\rho, T, \lambda) , \quad T = T(\rho, e, \lambda)$$

where  $\lambda$  is the degree of reaction (zero for no reaction and one for complete reaction) and  $p$ ,  $T$ ,  $\rho$ , and  $e$  are the pressure, temperature, density and specific internal energy.

For the equation of state we take the pressure to be a simple linear combination of the pressures which the individual components (reactants and products) would have at the given density and energy

$$p = (1 - \lambda)p_1(\rho, e + \lambda q) + \lambda p_2(\rho, e + \lambda q)$$

where  $p_1$  and  $p_2$  are the equations of state of the pure reactants and products and  $q$  is the heat of reaction.

For the function  $p_1$  describing the unreacted explosive we take the often-used form

$$p_1(\rho, e) = p_H(\rho) + \rho\Gamma(e - e_H(\rho))$$

in which the Grüneisen parameter  $\Gamma$  is assumed inversely proportional to the density (constant  $\rho\Gamma$ ) and the Hugoniot pressure and energy  $p_H$  and  $e_H$  are given by a Hugoniot (through the initial state) linear in  $U-u$

$$U = a + bu$$

$$p_H = \rho_0 a^2 n / (1 - bn)^2 , e_H = np_H / 2\rho_0 , n = 1 - \rho_0 / \rho$$

with  $U$  and  $u$  the shock and particle velocities.

For the function  $p_2$  describing the reaction products we use a  $\gamma$ -law

$$p_2(\rho, e) = (\gamma - 1)pe , \gamma \text{ constant} .$$

For the temperature, we take the temperature on the unreacted shock Hugoniot to be a linear function of pressure,<sup>2</sup> and get off this Hugoniot with a linear dependence of temperature on pressure at constant density.

$$T = T_0 + \alpha p_H(\rho) + \beta[p = p_H(\rho)]$$

This simple description puts the entire burden of calculating the mixture temperature on the unreacted component of the equation of state. To get reasonable temperatures at large amounts of reaction it is necessary to choose a larger value of  $\beta$  than that characteristic of the pure unreacted solid.

For the reaction rate, we use the first-order Arrhenius form

$$r = Z(1 - \lambda)e^{-T^+/T}$$

with constant activation temperature  $T^+$  and frequency factor  $Z$ .

### III. CHOICE OF PARAMETERS

The parameters are given in Table I. Values of  $\rho_0$ ,  $a$ ,  $b$ ,  $D$ , and  $\gamma$  are taken from experimental data and  $\Gamma$  is a guess. Subscript  $j$  denotes the CJ state.

For the temperature function we take the value of  $\alpha$  from Ref. 2 for TNT (no value is given for PETN). We estimate  $\beta$  as the ratio of the pressure and temperature differences between the CJ state and the unreacted shock Hugoniot at the CJ density  $\rho_j$

$$\beta = [T_j - T_H(\rho_j)]/[p_j - p_H(\rho_j)] ,$$

using an estimated value for  $T_j$  of 3000 K.

We decided to try the Arrhenius form for the rate when we noticed that the experimental gauge records suggested an initiation process similar to that calculated for an ideal gas with Arrhenius rate (but with stronger drive).<sup>3</sup> We determined the rate parameters by trial and error to approximately match the experimental gauge records. It is interesting to note that the ratios of the value of the exponential term  $e^{-T^+/T}$  at the CJ state to its value in the initial shock is roughly the same, about  $e^6$ , in both the present calculation and the ideal gas calculation of Ref. 3. Not surprisingly, the values of  $Z$  and  $T^+$  are very different from those determined from conventional heating experiments:  $Z = 6.3 \times 10^{13} \mu\text{s}^{-1} T^+ = 24000 \text{ K}$ . No doubt the shock-initiation mechanism is very different (plastic work, void-closing impact) and we have been fortunate to mock up even a portion of it with such a simple rate law.

The calculation uses a quartz driver plate; for its equation of state we use a two-piece version of the form used for the unreacted PETN, with the parameters given in Table I.

### IV. RESULTS

The calculation was performed with the one-dimensional Lagrangian hydrocode PAD.<sup>4</sup> From left to right, the body consists of a 6-mm slab of quartz impacting a 10-mm slab of PETN explosive. The dimensions are nominal: rarefaction from the front and rear surfaces do not affect the gauge histories over the time of the calculation. Gauges are placed at the left edge of the PETN and at distances of 2, 3, and 4 mm into it. These are ideal nonperturbing

TABLE I  
PARAMETERS<sup>a</sup>

PETN

$p(\rho, e, \lambda)$ :	
$\rho_0 = 1.7 \text{ mg/m}^3$	$D_j = 8.2 \text{ mm}/\mu\text{s}$
$a = 2.3 \text{ mm}/\mu\text{s}$	$\gamma = 2.9$
$b = 2.3$	$(p_j = 29.3 \text{ GPa})^b$
$\Gamma = 1.2$	$(\rho_0 q = 7.72 \text{ GPa})^b$

$T(\rho, e)$ :	$r(T, \lambda)$ :
$T_0 = 300 \text{ K}$	$Z = 150 \mu\text{s}^{-1}$
$a = 70 \text{ K/GPa}$	$T^\dagger = 3000 \text{ K}$
$\beta = 111.25 \text{ K/GPa}$	

Quartz

$\rho_0 = 2.65 \text{ mg/m}^3$ ,	$\Gamma = 1$
$a = 5.72$ , $b = 0$	for $\rho \leq 2.7174$
$a = 5.57$ , $b = 1.08$	for $\rho > 2.7174$

<sup>a</sup>The units are the coherent set based on mm, mg,  $\mu\text{s}$ .

$$b_{pj} = \rho_0 D_j^2 / (\gamma + 1) ; q = \frac{1}{2} D_j^2 / (\gamma^2 - 1)$$

gauges, that is, they simply record the particle (fluid element) histories at these points. (The pressures recorded by quartz gauges would, of course, be significantly higher because of the impedance mismatch.) At time zero, the moving slab of quartz with velocity 4 mm/ $\mu\text{s}$  impacts on the stationary PETN.

The program uses artificial viscosity to handle shocks. To have zero reaction rate in the quiescent state, we use an ignition pressure of 1 GPa to turn on the reaction. There are 200 computation cells in the quartz and 400 in the PETN. From two other runs with one-half and one-fourth as many cells and from other studies of the program's accuracy in solving the equations of motion (given the constitutive relations), we estimate typical errors to be 1-2% in pressure and particle velocity and 0.001 to 0.003 mm in position.

The computer output is given in the Appendix.

APPENDIX

COMPUTER RESULTS

The printout begins with the input data. Next are three printed snapshots at times 1.0, 1.375, and 1.75. Each begins with the last cell of the quartz and extends to the shock. The column labeled "TEMP OR S1" is temperature, that labeled "LAM OR S2" is  $\lambda$ , that labeled "VISCOSITY" is the artificial viscosity, and that labeled "C-SQ" is the square of the sound speed. Next are the particle histories (guage records).

The first set of graphs correspond to the printed snapshots, and the second to the printed particle

histories. The next graph, marked "OVERVIEW" is a t-x (time-distance) plot with dots marking particles. A pseudo-schlieren system picks up additional particles at large pressure gradients to mark waves. Again most of the quartz is omitted. The second OVERVIEW plots p and x for each point shown on the first, and connects those at the times listed under "OVERVIEW TIMES" at the end of the printout to form a sequence of superimposed p-x snapshot profiles.
